ASSESSMENT 3

AI Procurement Request Copilot

Build a small, reliable AI product - then prove which architecture you would ship.

01 Client challenge

THE SITUATION

Employees request new software and services. Procurement must check existing tools, team budget, vendor status, security/privacy requirements and approval rules. Build an AI-powered internal product that gathers evidence and recommends the next action - while keeping sensitive decisions with humans.

STARTER PACK PROVIDED

DATA	POLICY	MOCK SERVICE
Employees + budgets + software catalog + vendors + purchase history + requests	Procurement rules + approval thresholds + security / privacy requirements	Vendor / security status endpoint for tool-based retrieval

STARTER PACK [Download from Google Drive](https://drive.google.com/file/d/1rFJsf-VQK5fyQ9qzDjsw2tR0bACQujkA) | drive.google.com/file/d/1rFJsf-VQK5fyQ9qzDjsw2tR0bACQujkA

NOTE The starter code is a scaffold. If you encounter issues in it, you are expected to diagnose and fix them as part of the assignment.

02 Expected workflow

AI retrieves evidence. Deterministic checks stay in code where appropriate.

03 What you must build

A PRODUCT UI	B TOOL USE	C AGENT SYSTEM	D EVALUATION
Request details Evidence panel Recommendation + action	At least 3 tools At least 1 deterministic tool	Working single-agent baseline Structured outputs + human handoff	Compare with a staged / 2-agent variant Use the same test set

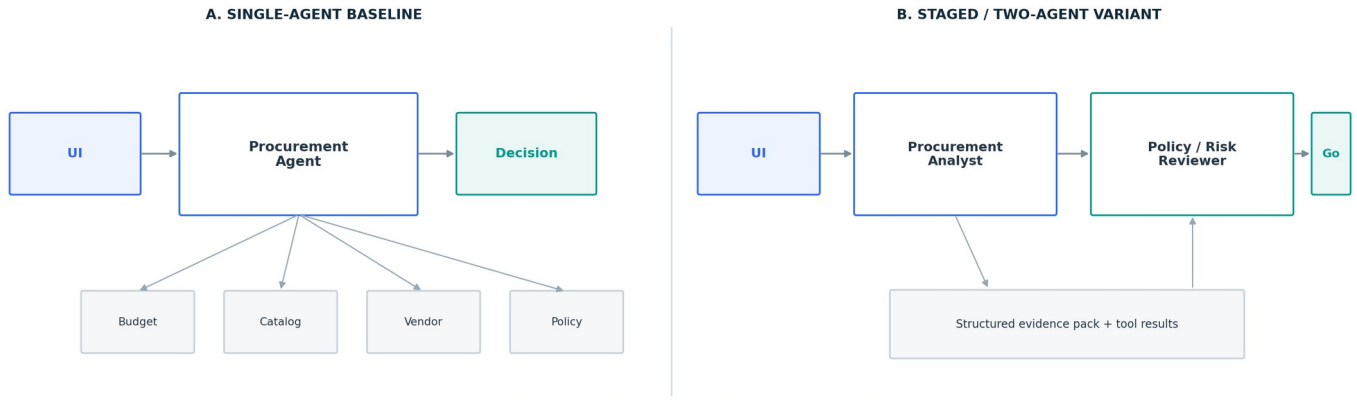

Required output: recommendation | evidence | approvals required | missing information | risk flags | next step

DESIGN PRINCIPLE

AI	CODE	HUMAN
Interpret context + recommend	Thresholds + deterministic checks	Sensitive approvals + exceptions

04 Architecture experiment

Build A first. Then implement a lightweight B and compare. Maximum recommended: 2 agents.

Run the same evaluation set on both. More agents do not earn more marks.

EVALUATE BOTH ARCHITECTURES

- Correct recommendation / next action
- Evidence is grounded in tool results
- Policy + deterministic rules are followed
- Escalation / human review is correct
- Latency + LLM/tool call count

EXPECT EDGE CASES

- Incomplete / ambiguous request
- Existing tool already solves the need
- Conflicting or expired vendor information
- Security-sensitive request or approval threshold
- Prompt injection inside business data
- Tool / API unavailable

05 Submission package

DELIVERABLES

- **Public GitHub repository**
- Working local app with a one-command start path
- Architecture / workflow diagram + assumptions
- Reproducible evaluation script and results
- Architecture decision memo - max 500 words
- No secrets in repo; include .env.example if needed

SCORING

Product + workflow	15%
End-to-end product	20%
Agent + tool design	20%
Reliability + human controls	15%
Evaluation + comparison	20%
Engineering + communication	10%

SUBMISSION CLOSES

8 Oct 2026

SUBMIT ON GOOGLE FORM

forms.gle/ab9DrohuNQWukXCD9

PUBLIC REPOSITORY + README REQUIRED The Google Form submission must contain your public GitHub repository URL. Your README should clearly cover setup/run steps, product workflow, architecture, tools/agents, assumptions, evaluation results, architecture comparison, final ship decision, and known limitations.

FINAL QUESTION

Which architecture would you ship - and why?

Use your evaluation evidence. A simpler system that performs as well or better is a stronger answer than unnecessary orchestration. UI polish and agent count do not earn extra marks by themselves.

BUILD	EVALUATE	DEFEND
Working vertical slice	Same test set on both	Evidence-backed choice
